

# **Forests, Climate and Green Economy:** *Biomass production and CO<sub>2</sub> sequestration*

**Univ.Prof. Dr. Hubert Hasenauer**

**Dipl.-Ing. Mathias Neumann**

**Institute of Silviculture,  
BOKU University of Natural Resources and  
Life Sciences Vienna/Austria**

## **Forests, Climate and Green Economy**

# **Introduction**

---

- **Main energy source are fossil fuels (coal, gas, oil)**
- **C stored in the lithosphere is released**
- **Leads to an CO<sub>2</sub> increase in the atmosphere**
- **Additional green house gases (methane, etc.)**
- **Increase in CO<sub>2</sub> results in an increase in temperature**
- **Air pollution effects (e.g. ozone)**

# Fossil Carbon release leads to an increase in global CO<sub>2</sub> concentration

“Dave Keeling” curve

*Without natural greenhouse gases:  
Mean temprature: -18°C instead of + 15°C*

# Distribution of anthropogenic C Emission

Canadell et al. 2007, PNAS

---

**45 % of CO<sub>2</sub> emissions stay in the atmosphere**

**55 % of CO<sub>2</sub> is accumulated**

**oceans (~ 25 %)**

**vegetation (~ 30 %)**

# Energy Production EU-27

## Year 2009

Source: EUROSTAT report 2012

# **EU Strategy for Renewable Energy**

## **The 2020 targets**

---

- **Increase share of renewable energy consumption to 20% (9.0% in 2009)**
- **10% share in transport sector**
- **Limit of food-based biofuel to 5 %**

# **Forests, Climate and Green Economy**

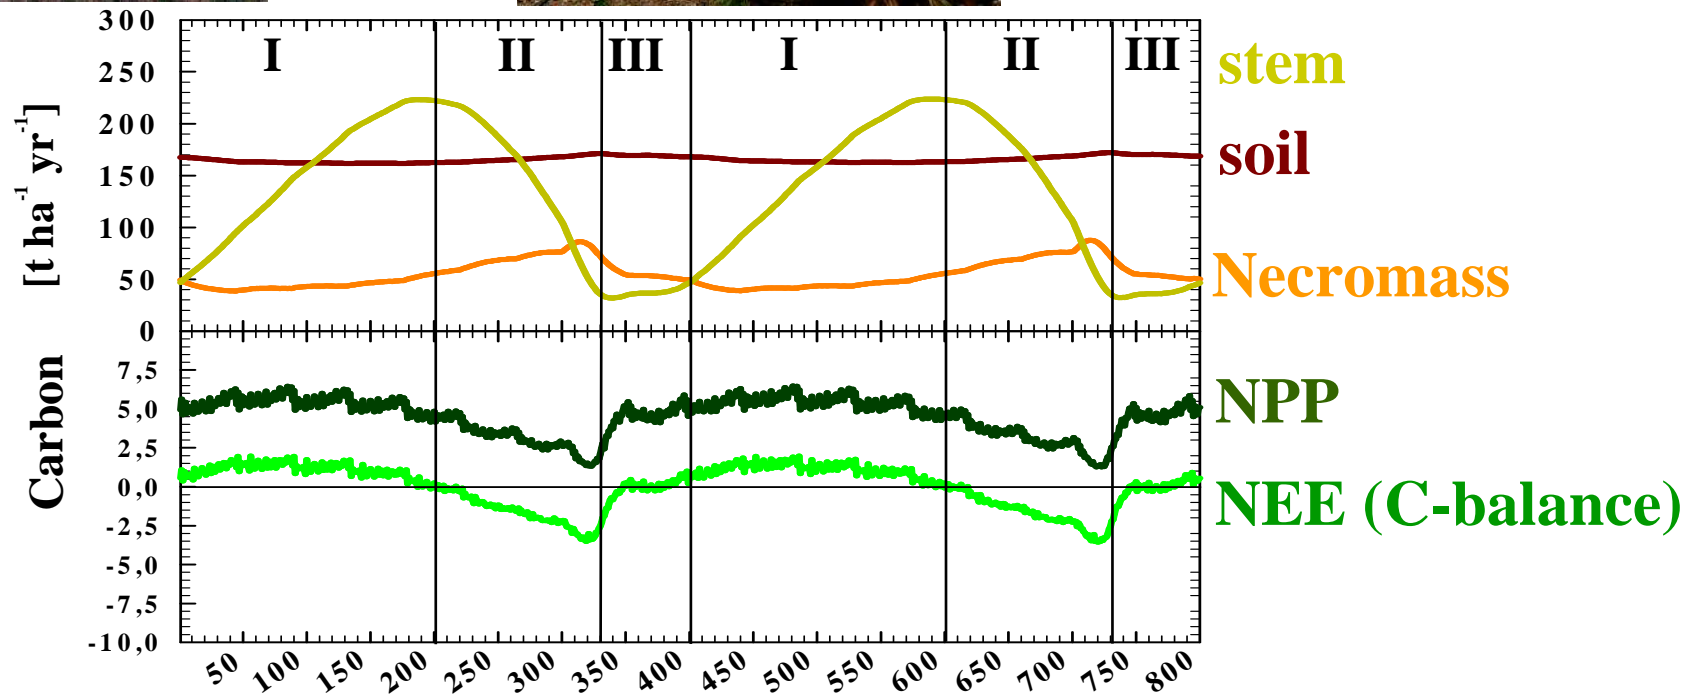

## **Carbon Cycle**

- 
- **Photosynthesis fixes carbon**
  - **Forests store large amounts of carbon**
  - **Disturbances release carbon**
  - **Forests are a renewable “energy source”**
  - **Forests are considered to be “carbon neutral”?**
  - **Management intensity is expected to increase**

# Carbon cycle in the Primary Forest

18 spruce-beech stands

Year

Pietsch & Hasenauer 2006

# Comparison of Primary Forest vs. Managed Forest

Source: Hasenauer et al. 2012

# What is a full carbon cycle?

# **There is a Debate going on that Forests are not “C neutral” – WHY?**

---

- **Increasing harvest leads to a reduction in the standing biomass**
- **This adds additional Carbon to the atmosphere**

**However ...**

- **Harvesting triggers growth/ carbon uptake**
- **Benefit of substitution of fossil fuels**
- **A complete life cycle assessment is needed**

## Forests, Climate and Green Economy

# Where do the Carbon Data come from?

---

- Forest inventories – measure tree volume (  $V \text{ m}^3/\text{ha}$  )
- Flux towers – measure flow of material
- MODIS satellite data – estimate NPP (  $C \text{ t/ha}$  )

# **Determining Carbon in Forests**

## **Expansion Factors or Functions**

---

- **Statistical – empirical approach**
  - (i) **Expansion factors for volume into carbon**
  - (ii) **biomass functions to predict carbon**
- **Typical procedure for Forest inventory data and population models**

# **Determining Carbon in Forests**

## **Explicit Carbon Cycle**

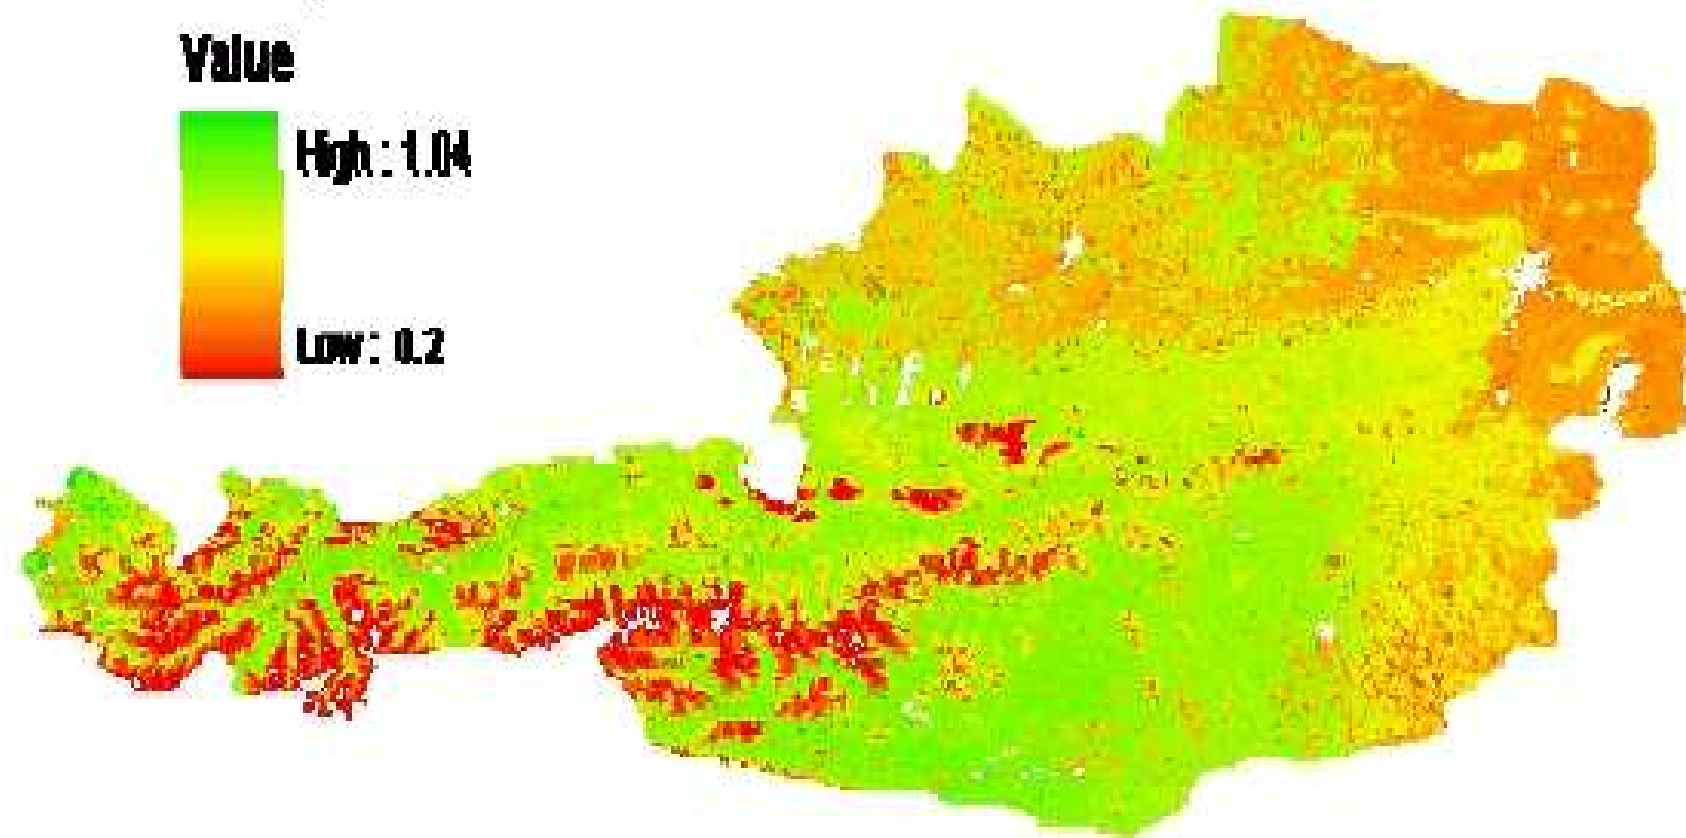

---

- **Biogeochemical-mechanistic approach**
- **Photosynthesis routine to assess the flux dynamics (C, Water, N, and Energy Cycle) within forests**
- **Typical procedure in BGC-Models**

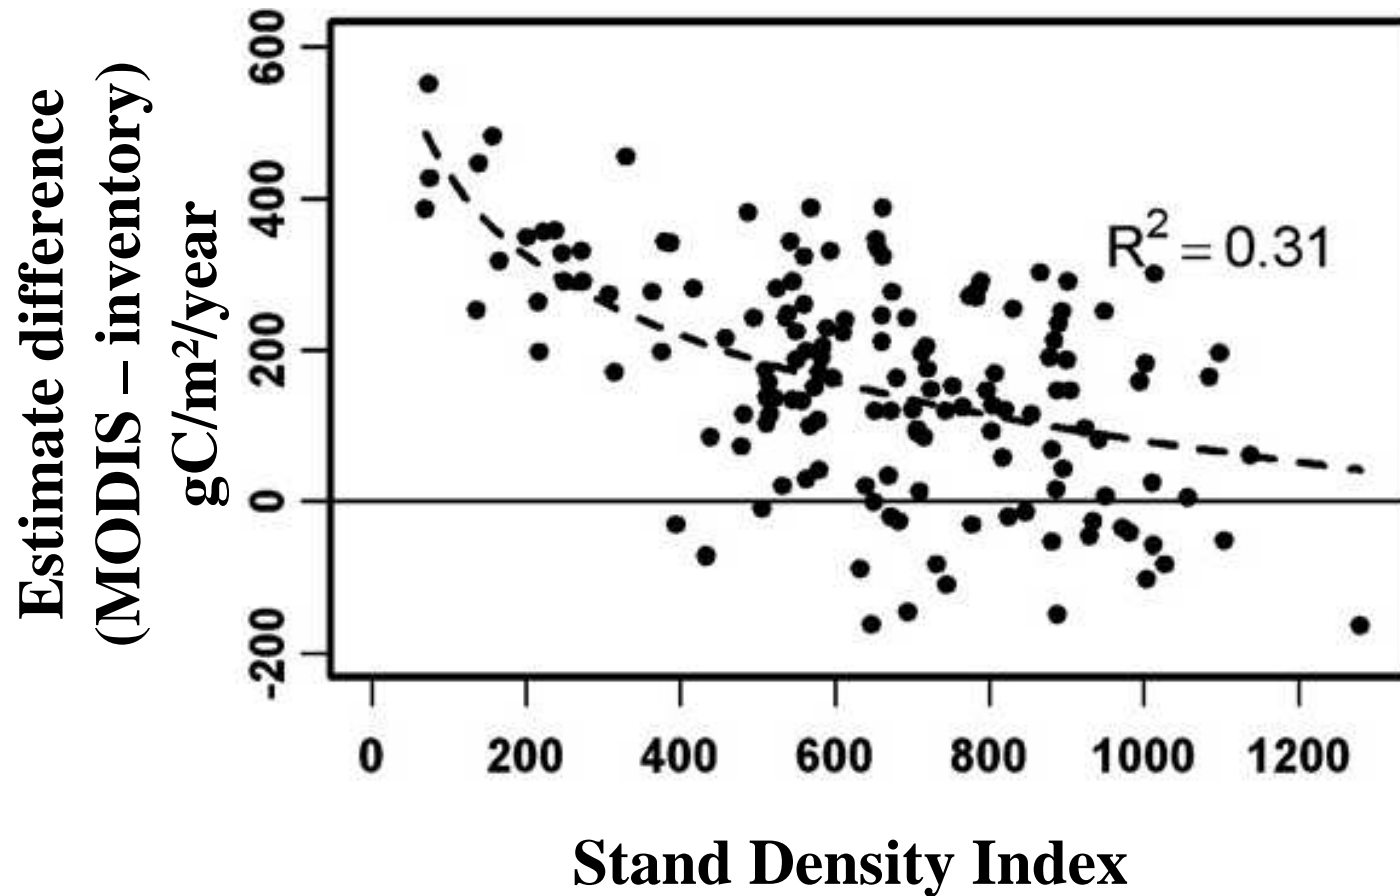

## From MOD17 NPP (2002-2007)

**NPP kgC/m<sup>2</sup>/yr** With a biomass function and tree datas  
- estimation of NPP

# Difference of MODIS NPP and NPP from inventory data

# After consideration of stand density, NPP estimations are consistent

Hasenauer et al. 2012

**Forests, Climate and Green Economy**

## **Why Forest biomass – Summary ?**

---

- **Use of biomass substitutes fossil carbon sources**
- **CO<sub>2</sub> release will be fixed through photosynthesis**
- **Annual biomass increment is higher then annual cut**
- **Generates income in rural areas**
